The relationship between causality and science takes a modern turn with Galileo, whose Two New Sciences appeared in 1632, twelve years after the New Organon. Galileo recognizes that science concerns quantifiable relations among phenomena. He does not deny causality; rather, he sets the issue aside and gets on with pragmatic description.

: The issue of causality in epidemiology is complex and involves the application of several causal criteria. The greater the number of causal criteria that are satisfied by an observed association, the greater is the likelihood of a causal relationship. The epidemiologist must rule out chance, which may account for observed associations.

Causality is measured as the time rate of information flowing from one time series to another. It has long been recognized that a nonzero IF, or information transfer as it may appear in the literature, from an event to another logically tells the strength of the causality from the former to the latter, and a vanishing causality must entail a ...

The Granger causality test is a statistical hypothesis test for determining whether one time series is useful in forecasting another, first proposed in 1969. Ordinarily, regressions reflect "mere" correlations, but Clive Granger argued that causality in economics could be tested for by measuring the ability to predict the future values of a time series using prior values of another time series.
